

Earthquake Hazards in Eureka and White Pine Counties

Presentation by Craig M. dePolo and Jonathan G. Price
Nevada Bureau of Mines and Geology

Nevada Hazard Mitigation Planning Committee

8 May 2012

Earthquakes in the Eureka region

Earthquakes in Austin and Eureka 1868-1894

- 1st reported event in Austin Nov. 7, 1868; eight more through 1894,
- M 5.5 near Austin March 23, 1872, plaster fell in courthouse,
- M 6 south of Austin Nov. 12, 1872, sharp shock.

- April 11, 1872 slight shock Eureka,
- Nov. 8, 1873 quaking last couple of
 nights, quite a perceptible
 quiver for several seconds,
- April 2, 1875 severe Eureka M5+.
- Dec. 8, 1881 heavy shock in Eureka

April 2, 1875

~6:00 pm; about 3 secs. Shaking,

“brought to the feet every man, woman, and child in town. Everyone rushed frantically to the streets, and not a few clambered up the hill-sides for safety, fearful that the town was about to be demolished”

Eureka Daily Sentinel 4/2/1875

MMI = VII, Slemmons and others (1965)

**Earthquake faults occur throughout Nevada,
and potential losses from earthquakes are high
for many communities,
including Eureka and Ely.**

**Earthquake faults occur throughout Nevada,
and potential losses from earthquakes are high
for many communities.**

**NBMG Map 167, *Quaternary Faults in Nevada*, is now
available not only as a poster but also as an interactive
map (Open-File Report 09-9) on line at
www.nbmг.unr.edu. You can use it to locate your home
or business.**

Age of Latest Fault Rupture

< 150 years (historical)

< 15,000 years

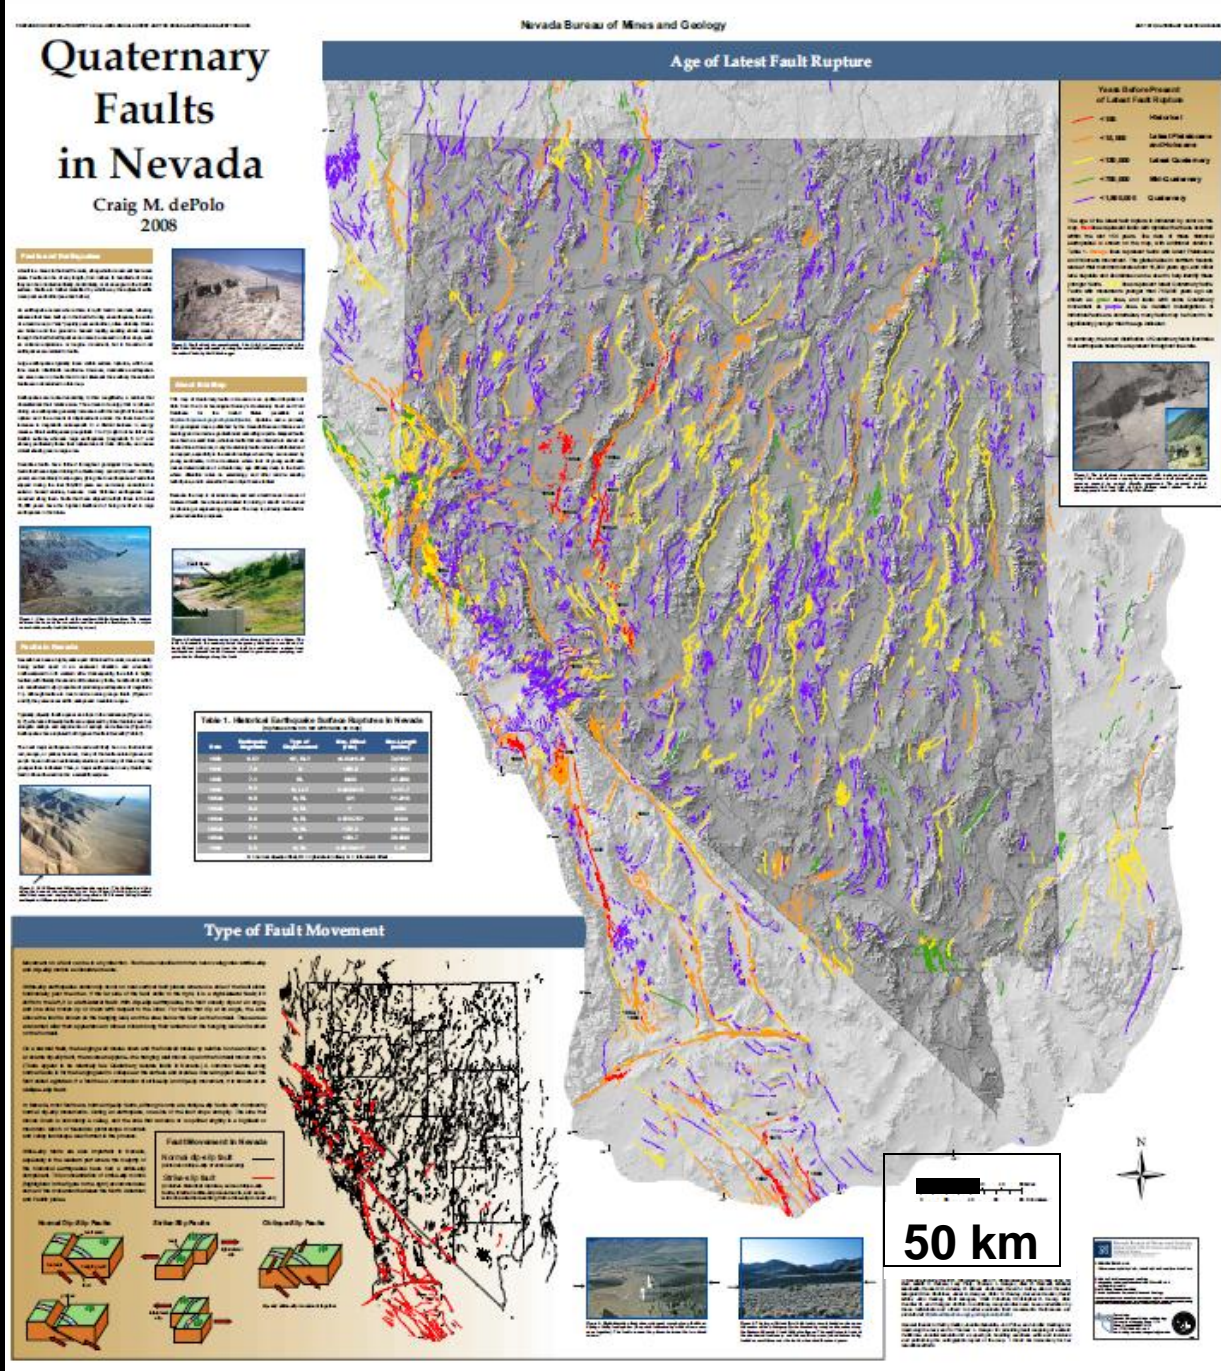

< 130,000 years

< 750,000 years

< 1,800,000 years
(Quaternary)

There are active faults nearly everywhere in Nevada.
A magnitude 6.0 earthquake can occur anywhere in Nevada.

(1) There are active faults nearly everywhere in Nevada, including Eureka and White Pine Counties.

Wells
21 Feb 08
M = 6.0

(2) Earthquakes have occurred throughout Nevada.

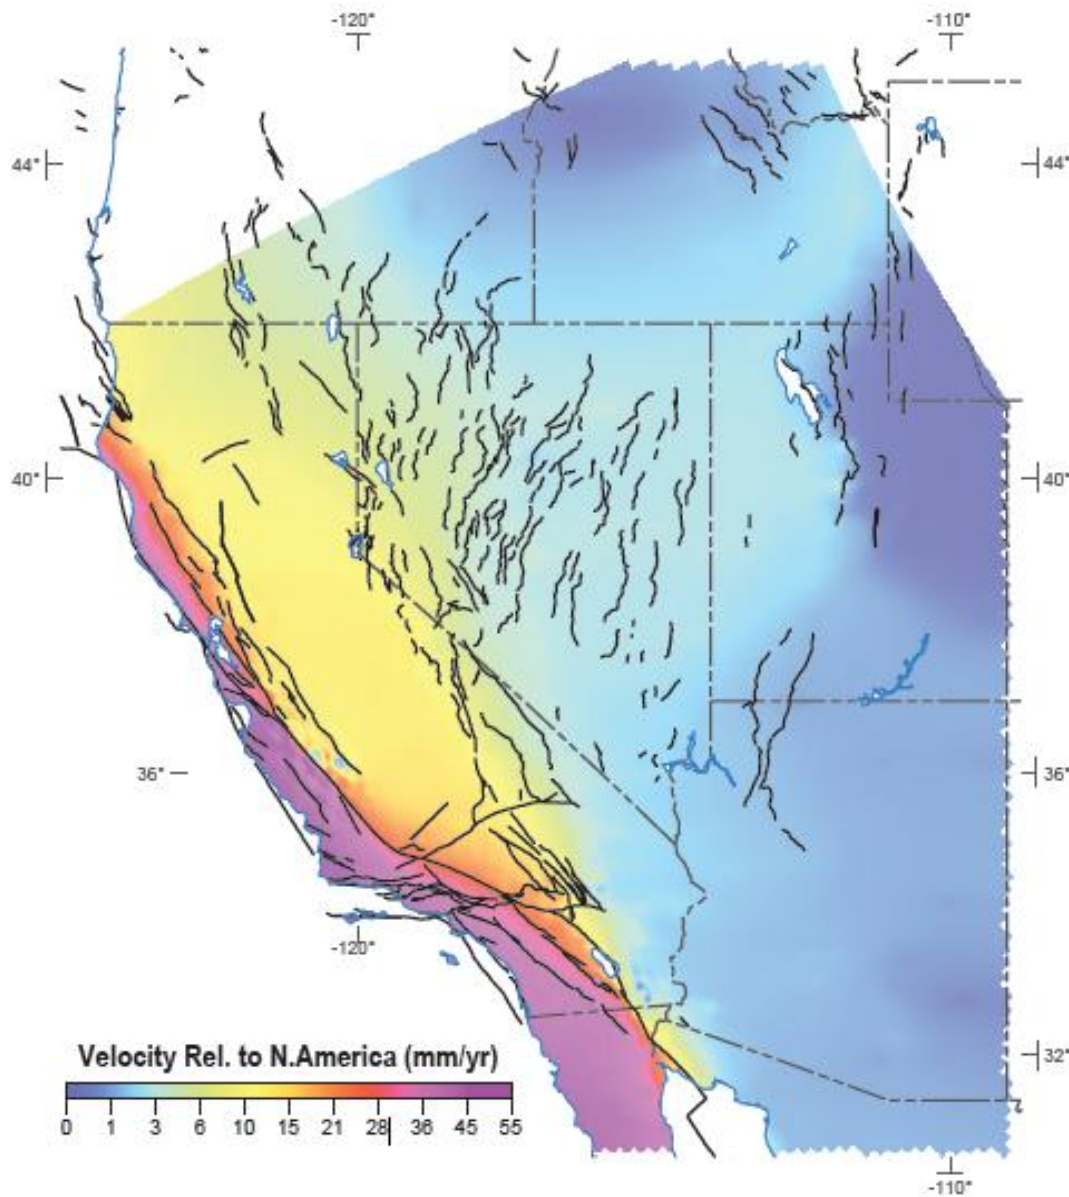

Uncertainty is high in areas with few geodetic GPS data points (areas in blue on this map).

Signal-to-noise (SNR) ratio defined as the ratio of second invariant of the strain rate over the a posteriori standard deviation. These values are strongly affected by the GPS station density and the precision of velocities. Everywhere where $SNR < 1$ the area could be considered rigid within one standard deviation. Conversely, for areas that the model suggests are nearly rigid and where $SNR < 1$ (e.g., Arizona, eastern Nevada) strain rates may be much more localized (i.e., higher) than the model suggests.

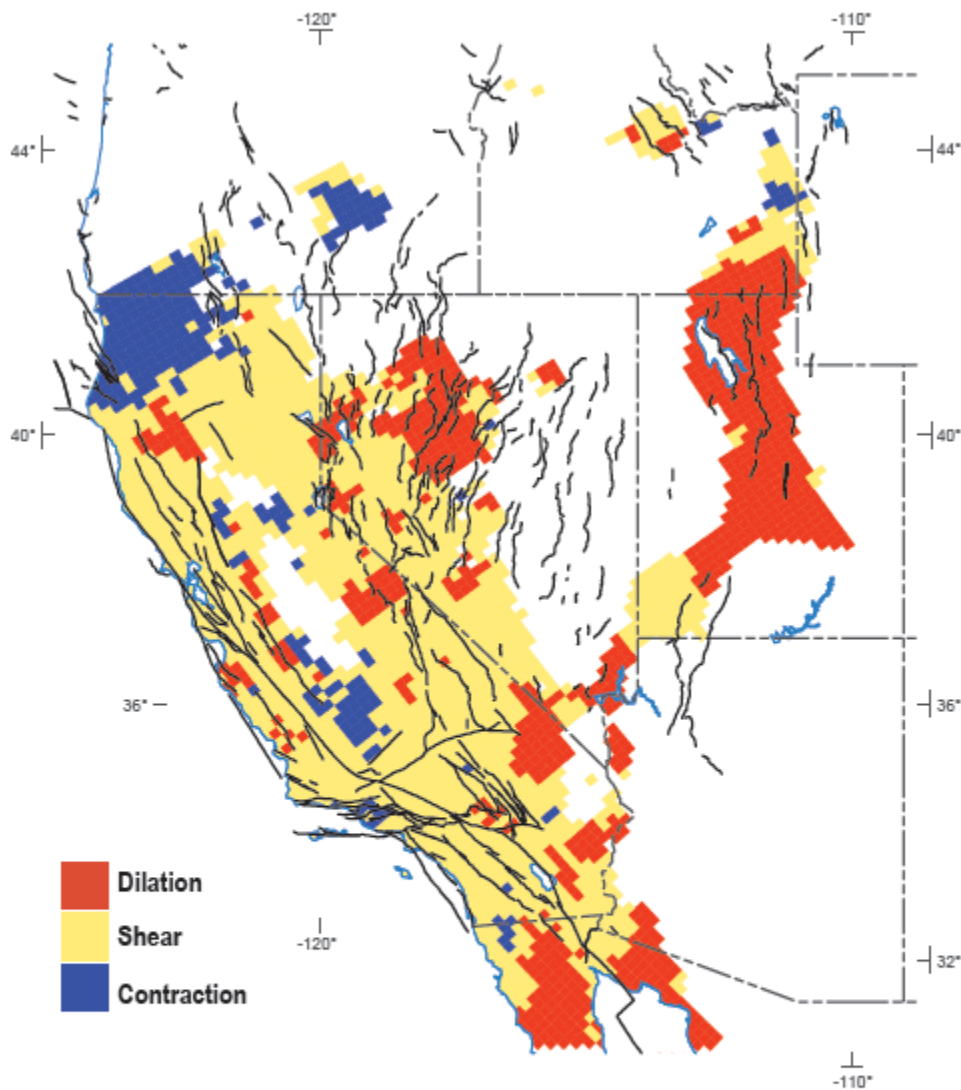

West of the San Andreas fault in California, the Pacific Plate is moving northwest relative to the North American Plate.

Contour map of the amplitude of interpolated velocities relative to North America.
Results are clipped at coast.

Kreemer et al. (2012)

General style of deformation for all areas where at least one strain rate principal component is > 6 nanostrain/yr. Results are spatially averaged. We define shear where the largest absolute principal value is less than twice the smallest absolute principal value. If not shear, we define dilatation or contraction when the largest principal value is positive or negative, respectively. Results are clipped at coast.

Western Nevada is accommodating ~20% of the North American-Pacific plate interaction, mostly along right-lateral strike-slip faults and oblique-slip normal faults.

Extension is occurring mostly in western and central Nevada (and along the Wasatch front in Utah) along normal faults.

State	Surface Growth (acres/yr)
AZ	0.08
CA	-0.96
NV	0.20
UT	0.21

The negative value for California indicates shrinking, not growing.

Nevada and Utah are growing.

A Geodetic Strain Rate Model for the Pacific-North American Plate Boundary, Western United States

University of Nevada Reno
²Department of Geological Sciences,
University of Arizona

2012

SUMMARY

The map presents a geodetic strain rate model for the Pacific-North American plate boundary in the western United States. The model is based on GPS data and is presented as a color-coded map showing the distribution of strain rates across the region. The map is overlaid on a topographic map of the western United States, showing the Pacific-North American plate boundary and major faults. The map is color-coded to show strain rates ranging from 0.1 to 0.3 mm/yr. The map is overlaid on a topographic map of the western United States, showing the Pacific-North American plate boundary and major faults. The map is color-coded to show strain rates ranging from 0.1 to 0.3 mm/yr.

GPS DATA

The GPS data used in this study were collected from 1994 to 2008. The data were collected from 1,000 GPS stations across the western United States. The data were used to calculate the strain rate model. The data were collected from 1,000 GPS stations across the western United States. The data were used to calculate the strain rate model.

MODELING DETAILS

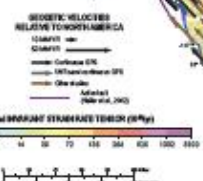

The strain rate model was calculated using a finite element method. The model was based on the GPS data and was used to calculate the strain rate model. The model was based on the GPS data and was used to calculate the strain rate model.

State	Surface Growth (mm/yr)
AK	0.05
CA	0.08
WY	0.25
UT	0.21

(3) Geodetic data indicate that the Nevada is gaining about 0.2 acre of area per year through crustal extension, and that western Nevada is accommodating ~20% of the North American-Pacific plate interaction.

Kreemer et al. (2012)

In Nevada, much of the right-lateral shear between the North American and Pacific plates occurs along northwest-striking strike-slip faults of the Walker Lane.

Extension largely is accommodated along N- to NE-striking, basin-bounding normal faults.

Walker Lane

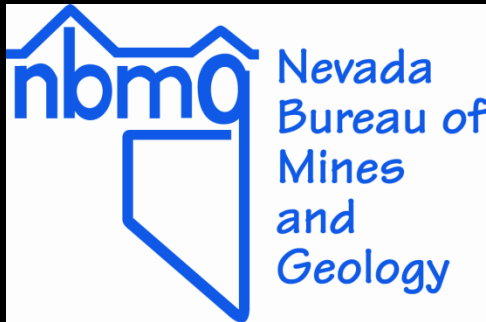

The hazard: expressed in terms of probability of an earthquake of a given magnitude occurring within 50 years and within 50 km of the community.

Community	% Probability of magnitude greater than or equal to magnitude				
	5.0	5.5	6.0	6.5	7.0
Dayton	>90	~80	70-75	50-55	12-15
Carson City	>90	~80	70	50-55	12-15
Reno	>90	~80	67	50	12-15
Fallon	80-90	~60	35	20-25	6-8
Las Vegas	40-50	~30	12	4-5	<0.5
Eureka	40-50	~30	10-15	4-6	<0.5
Wells	30-40	~20	9	6	0.5-1
Ely	20-30	~15	4-6	1.5-2	<0.5
Laughlin	10-20	~5	2-3	0.5-1	<0.5

Data are from the USGS at <http://eqint.cr.usgs.gov/eqprob/2002/index.php> .
 Values for magnitude 5.5 are extrapolated between 5.0 and 6.0.

Earthquake faults occur throughout Nevada,
and **potential losses from earthquakes are high
for many communities.**

NBMG Open-File Report 09-8, *Estimated Losses from Earthquakes near Nevada Communities*, demonstrates that the consequences of earthquakes can be huge in Nevada, particularly if individuals are not prepared.

Earthquake risks in Nevada are assessed by the Nevada Bureau of Mines and Geology using the Federal Emergency Management Agency's loss-estimation model, HAZUS-MH, and the U.S. Geological Survey's probabilistic seismic hazard analysis.

These loss estimates are useful in hazard-mitigation planning, in building scenarios for emergency response and recovery exercises, and in helping emergency managers and the Governor make decisions on official disaster declarations after an actual earthquake.

LYON COUNTY, DOUGLAS COUNTY
STORSEY SE - VIRGINIA CITY +
INDUSTRIAL DISTRICT
AFTERSHOCKS POSSIBLE-

Earthquake risks in Nevada are assessed by the Nevada Bureau of Mines and Geology using the Federal Emergency Management Agency's loss-estimation model, HAZUS-MH, and the U.S. Geological Survey's probabilistic seismic hazard analysis.

NBMG Open-File Report 09-8, *Estimated Losses from Earthquakes near Nevada Communities*, contains HAZUS scenarios for magnitude 5.0, 5.5, 6.0, 6.5, and 7.0 earthquakes near 38 communities in Nevada.

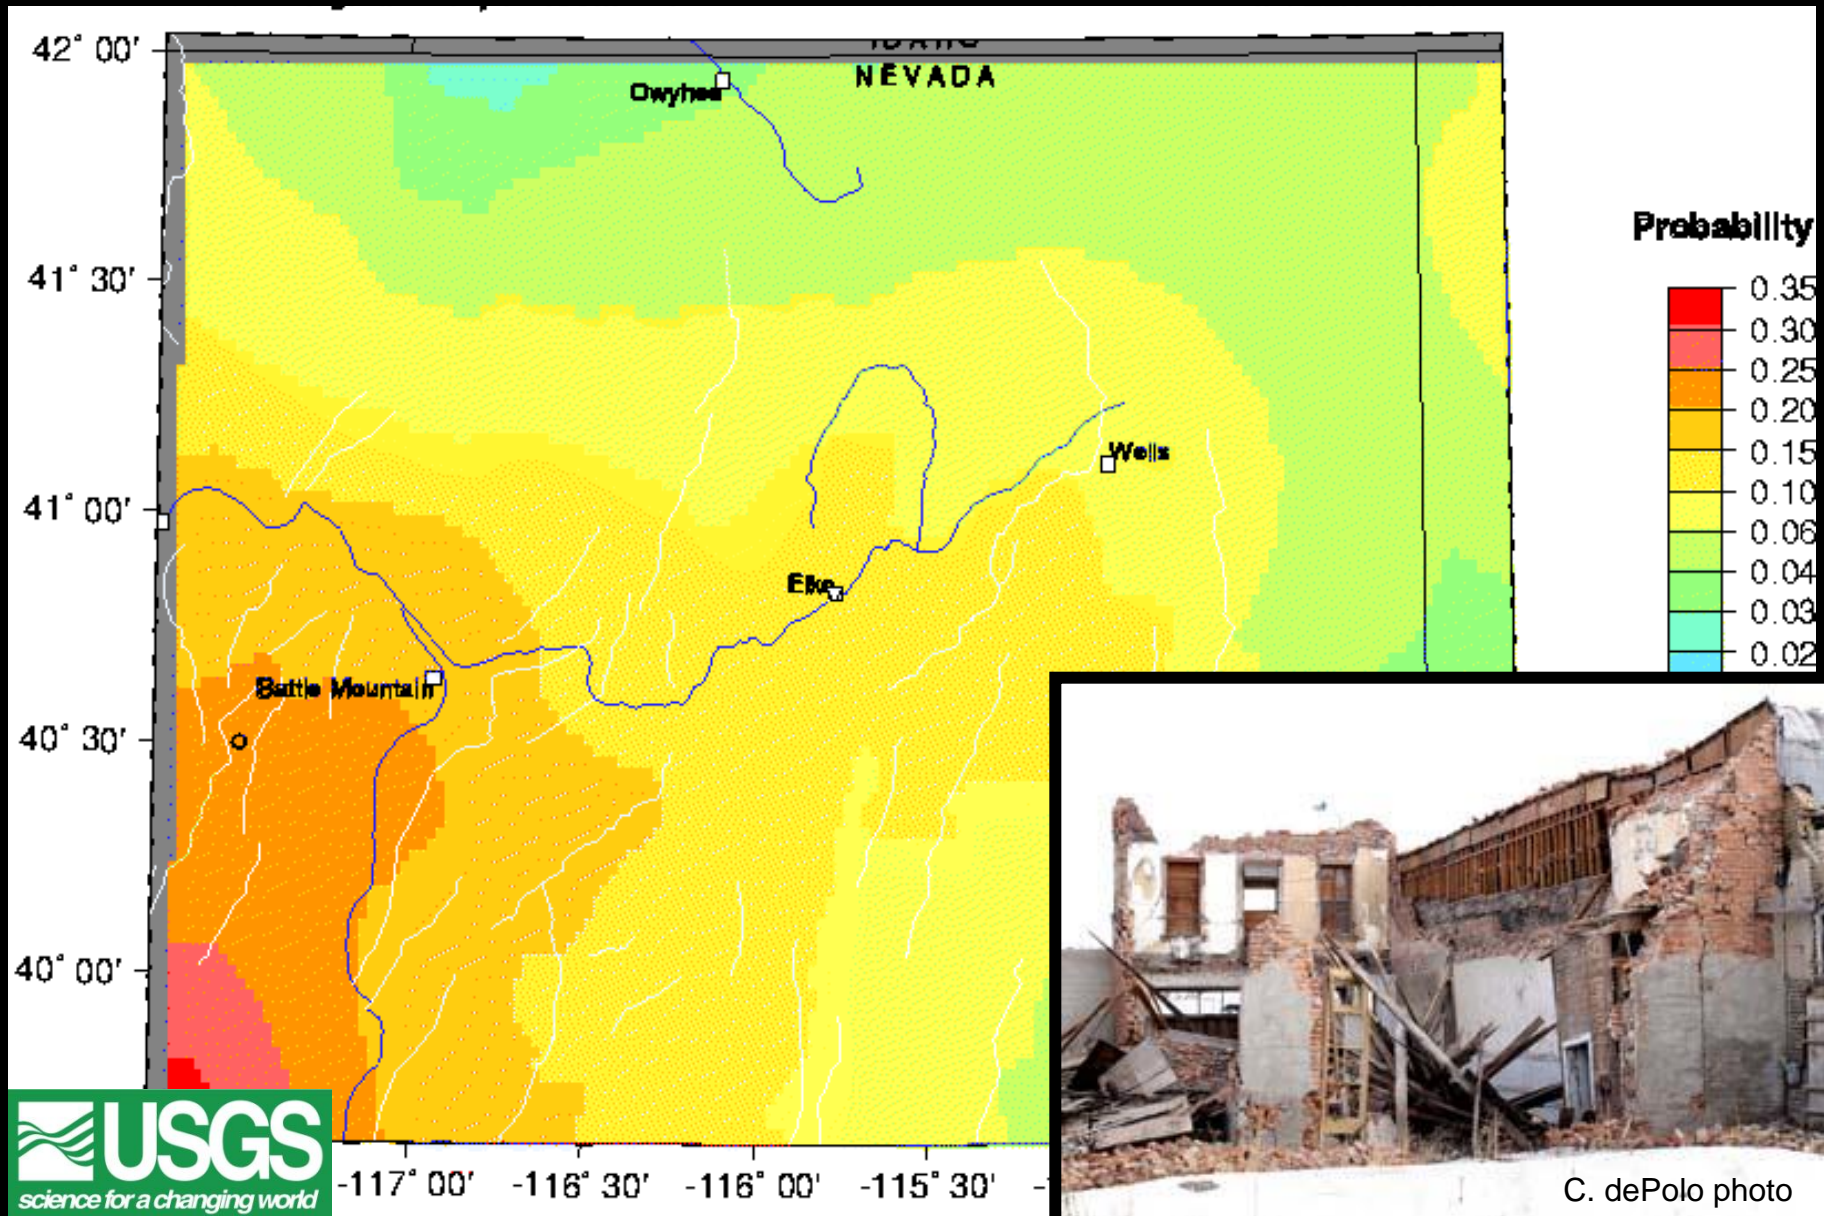

Uncertainties in the location of epicenters, depths, and magnitude, when combined with changing population and uncertainties in local effects (soil and rock types, assumptions about attenuation, basin geometry, liquefaction potential, and directivity), make loss estimates generally consistent within one order of magnitude (a factor of 10), although experience with urban earthquakes in the US has generally yielded numbers within a factor of 2 or 3 of the actual damages.

HAZUS estimates for total economic loss from a magnitude 6.0 earthquake and probability of an earthquake of this magnitude or greater occurring within 50 years and within 50 km of the community.

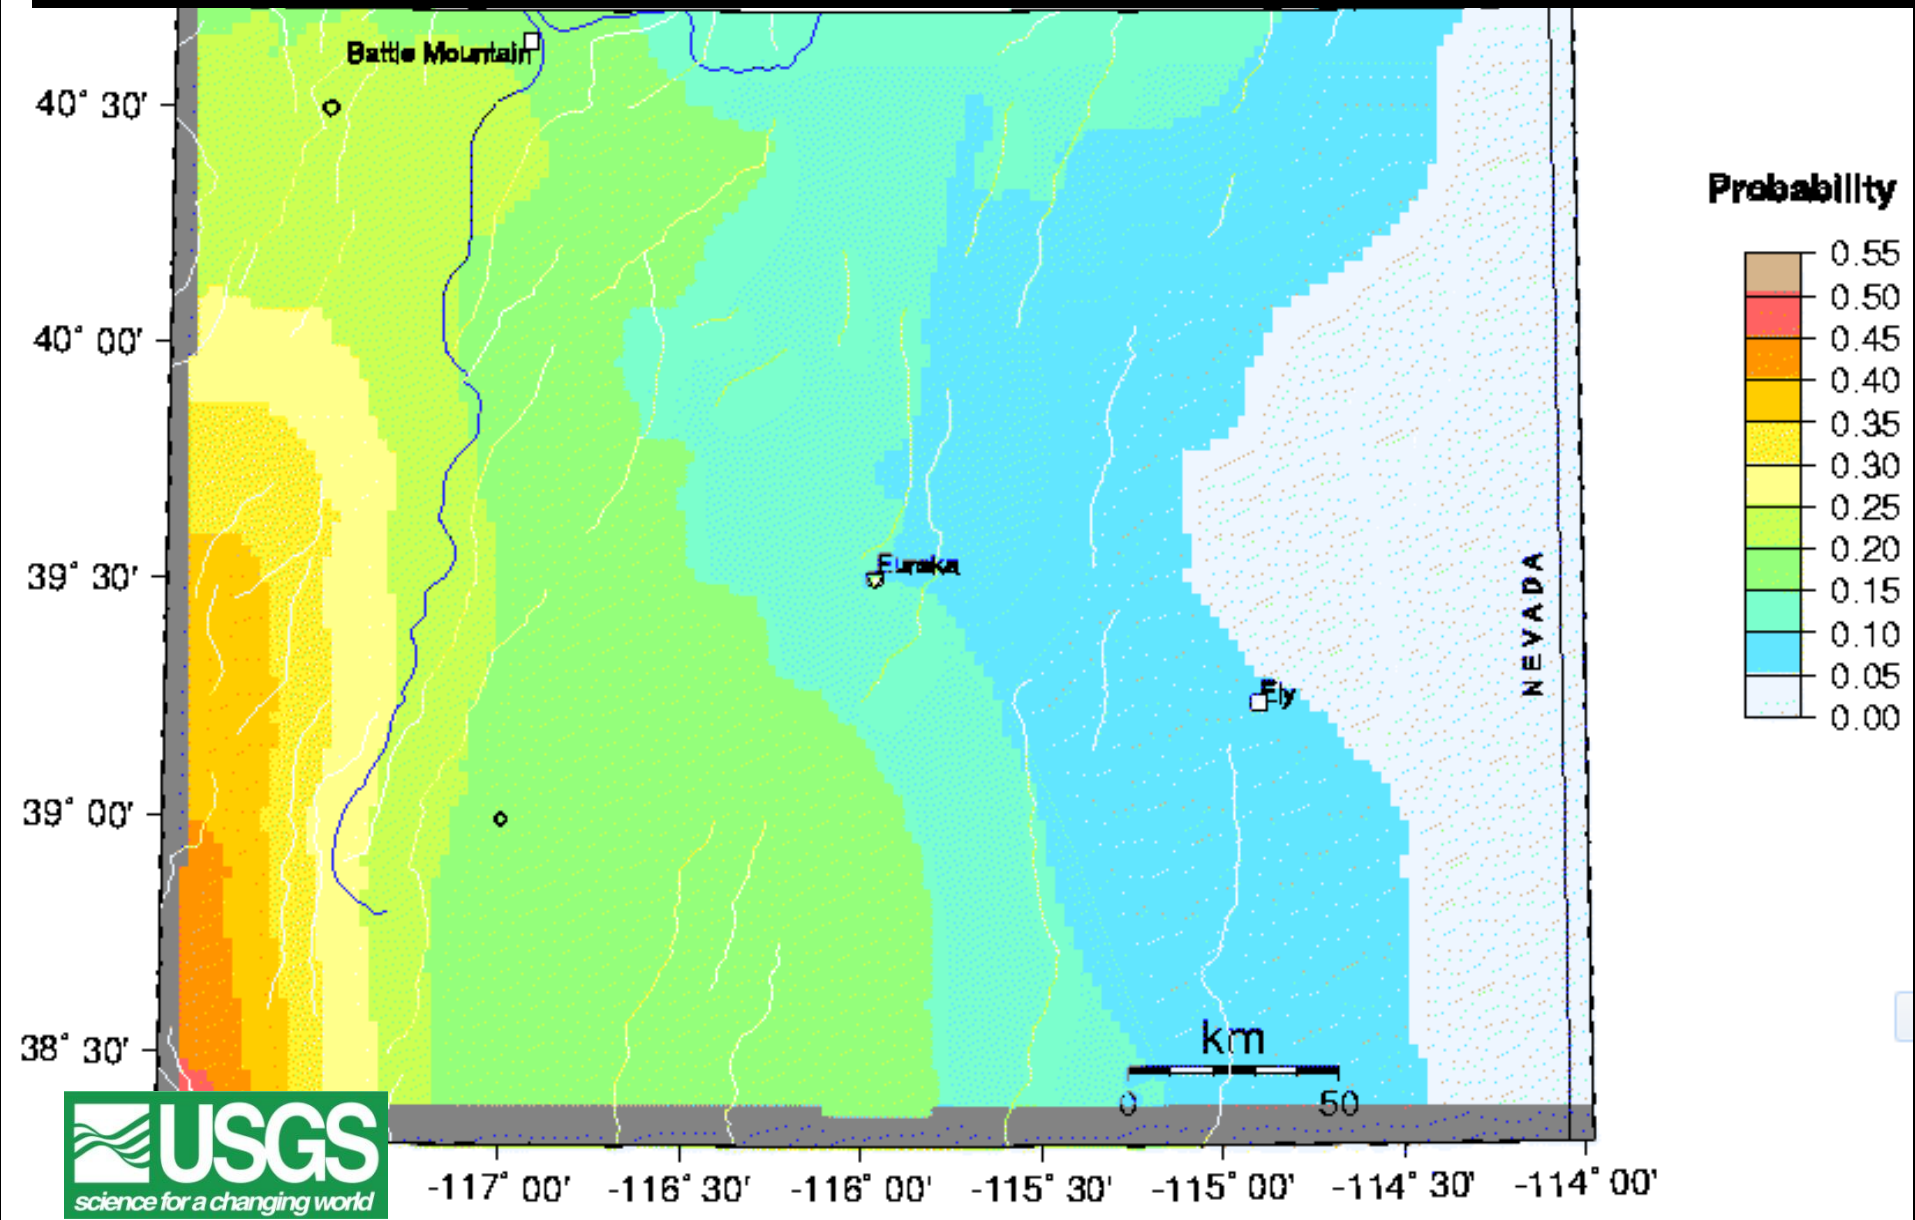

Community	Total Economic Loss	Probability in 50 years within 50 km
Las Vegas	\$7.2 billion	12%
Reno	\$1.9 billion	67%
Carson City	\$650 million	70%
Elko	\$160 million	10 to 15%
Fallon	\$110 million	35%
Ely	\$44 million	4 to 6%
Eureka	\$34 million	10 to 15%
Wells	\$30 million	9%

Total economic loss is from HAZUS. Probabilities are from the USGS at <http://eqint.cr.usgs.gov/eqprob/2002/index.php> .

The probability of a magnitude 6.0 earthquake occurring within 50 km of Wells, Nevada within the next 50 years is approximately 9%.
It happened on 21 February 2008.

The probability of a magnitude 6.0 earthquake occurring within 50 km of Eureka within the next 50 years is approximately 10%, about the same as Wells; Ely's probability is approximately 5%.

Earthquake faults occur throughout Nevada, and potential losses from earthquakes are high for many communities.

The consequences of earthquakes can be huge in Nevada, particularly if individuals are not prepared.

A. Be prepared to respond. (Make a plan; assemble a kit; stay informed.)

B. Mitigate structural risks, largely through building codes and avoiding faults and areas of liquefaction.

C. Mitigate nonstructural risks.

San Marin Hotel, an unreinforced masonry building (URM) that collapsed during the Wells, Nevada earthquake

Unreinforced masonry building (URM)
that collapsed during the Wells
earthquake on 21 February 2008

View from back, 20 May 2009

View from front, 20 May 2009

Definition of potential unreinforced masonry (URM) buildings in Nevada:

buildings listed by County Assessors or State Public Works as built before 1974 with brick, stone, or block masonry structure.

Caution: This is a preliminary study based on data provided by the County Assessors and the State of Nevada. We know there are errors in the database:

URMs missed - not recorded as masonry structures

URMs missed – ones on federal or Indian lands

URMs counted due to wrong building type in the database

Wrong locations due to poor address coding

Misidentifications due to lack of construction date

Buildings that may have been seismically retrofitted

Buildings that have been removed.

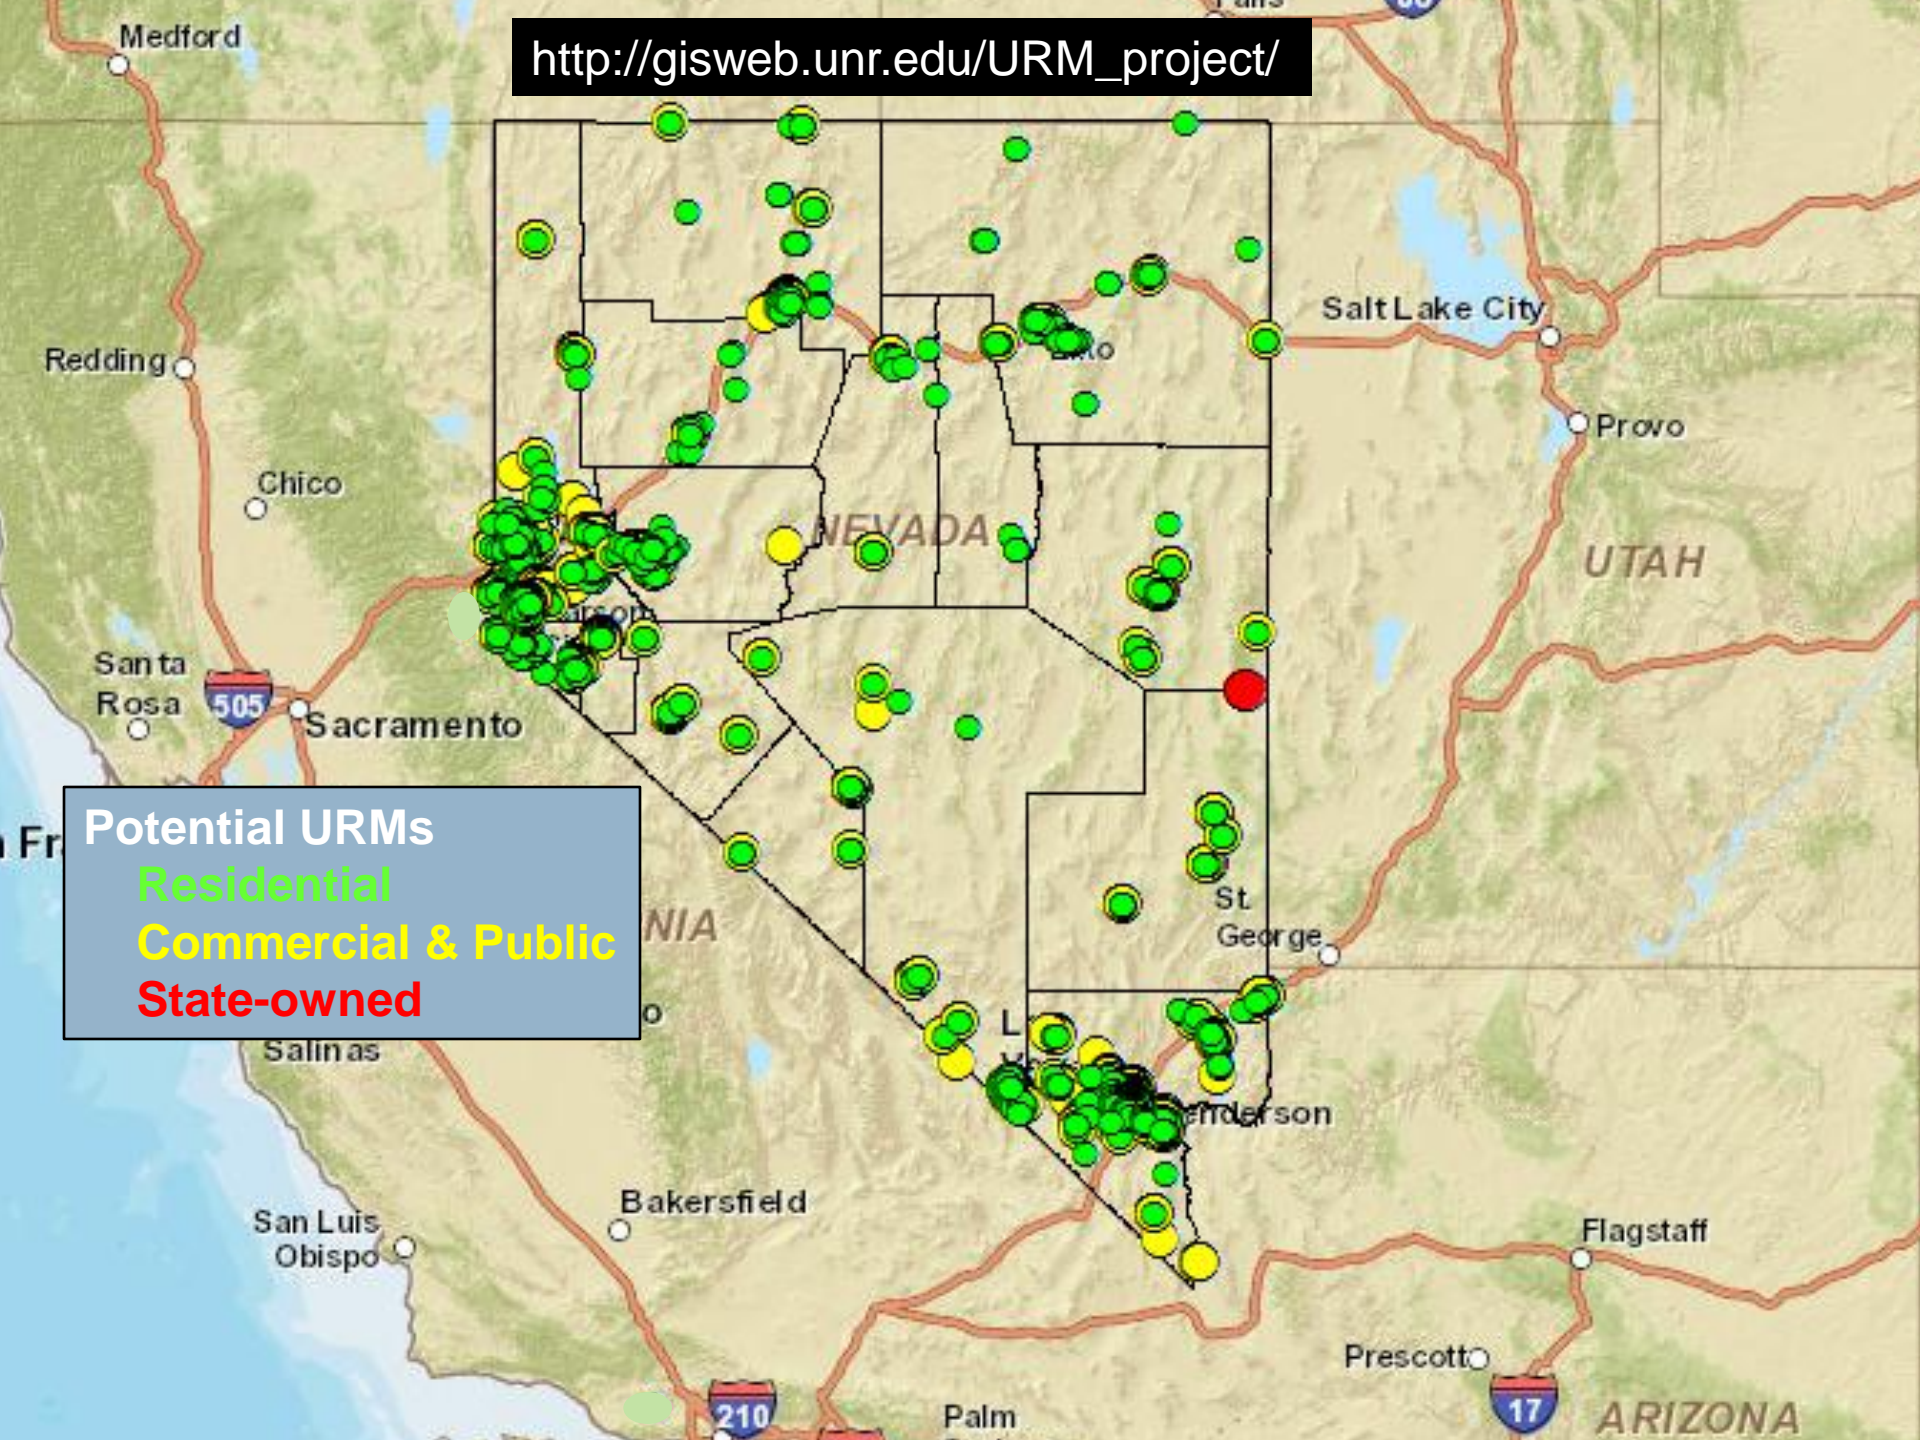

Recommendation 1 (draft): Jurisdictions (cities, counties, state) should use this County Assessors' data to follow up with on-the-ground inspections and checks of building plans. Individuals should determine if their buildings are URMs. Everyone should recognize that some URMs are missing from the database and that some buildings listed are actually adequately reinforced.

Potential URMs in Nevada – totals*

7,354	Residential
16,145	Commercial & Public (city and county)
<u>98</u>	State-owned
23,597	TOTAL*

* The total does not include buildings owned by the federal government.

http://gisweb.unr.edu/URM_project/

Observations:

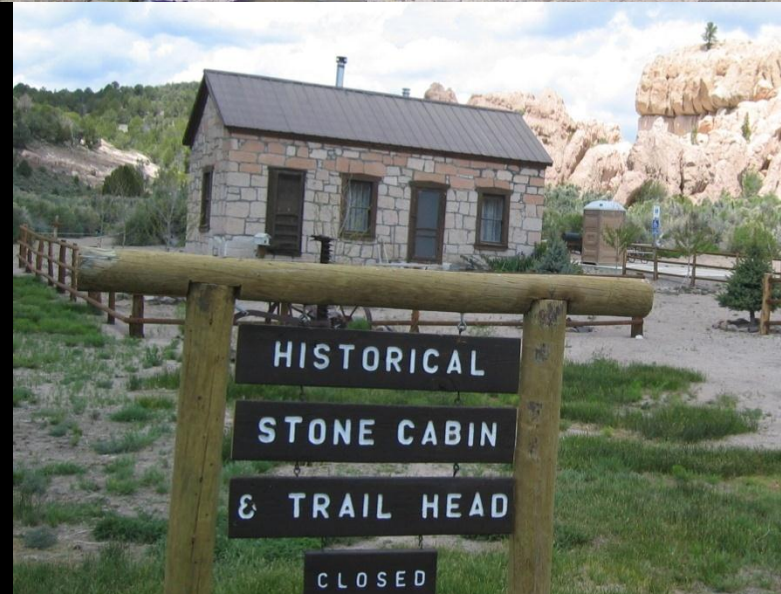

Because URMs are mostly 50+ years old, many have deteriorated and need maintenance. Some may have been damaged from shaking during previous distant or small earthquakes.

Many of the potential URMs in Nevada are historical buildings. Many are concentrated in downtown business districts and along thoroughfares. Experience from recent earthquakes demonstrates that collapse of these buildings or their facades not only can cause deaths and injuries but also disrupt emergency vehicles during earthquake response and slow business recovery in the weeks and months after the earthquake.

Historical stone cabin, built in the 1870s with blocks of tuff from nearby outcrops, Spring Valley State Park, Lincoln County.

Potential injuries to people are minimized by preventing visitors from going inside.

Manzanita Hall on the UNR campus, URM residence hall with 97 students, built in 1896, scored 0.4 out of 7 in 2005 preliminary seismic screening.

Recommendation 2 (draft): Jurisdictions should work toward seismically retrofitting URM's or removing them from human occupancy. They can take advantage of opportunities for federal funding for mitigation. Buildings should be brought up to current code when remodeling. They can learn from what other jurisdictions have done successfully, such as providing incentives for individuals and businesses to retrofit URM's or replace them with new buildings.

Unreinforced masonry building (URM) that collapsed during the Wells earthquake on 21 February 2008

Nonstructural damage often can be easily prevented.
