

Geothermal Resources of Colorado

GEOTHERMAL RESOURCES OF COLORADO

RICHARD HOWARD PEARL

Colorado's geothermal resources are varied in character and scattered in the western half of the State. In recent years most geothermal exploration has been directed toward high-temperature (>150°C) resources and has not spared the intermediate-temperature (90-150°C) and low-temperature (<90°C) systems. Three high-temperature areas are now being evaluated: at Mount Princeton Hot Springs, Poncha Hot Springs, and Cripple Hot Springs. Numerous intermediate- and low-temperature resource areas can be exploited for varied significant uses and are expected to supply a large part of the State's energy needs in the years to come.

There are approximately 130 thermal springs and wells in 28 areas of western Colorado. The temperature range is generally from 20°C (68°F) in some areas to a high of 83°C (181°F) at Hotwater Hot Spring (Mount Princeton). Discharge rates are less than four l/min (liters per minute) at Cripple Hot Spring and Browns Canyon Warm Spring to more than 8300 l/min at Cripple Hot Springs. Dissolved mineral matter ranges from 0.6 mg/l (milligram per liter) at Eldorado Warm Springs to a high of over 21,000 mg/l at Cripple Hot Springs.

Accessible resource base: Barrett and Pearl (1978), using various geothermometer techniques, have estimated subsurface temperatures of all the known thermal areas in Colorado. Their calculations indicate reservoir temperatures from a low of 20°C at several sites to over 200°C at Mount Princeton, Waunila, and Poncha Hot Springs. In attempting to define the accessible resource base, Pearl (1979) made basic assumptions on dimensions and calculated the quantity of heat that could be contained in each thermal area. The calculations show there may be as much as 5 x 10¹⁰ to 3 x 10¹¹ Btu (1.37 x 10¹⁰ to 3.5 x 10¹⁰ joules) of heat energy contained in the thermal systems of the State. Although no thermal springs or wells have been reported in eastern Colorado, preliminary information from oil and gas wells indicates areas of above normal (>20°C) geothermal gradients in northeastern Colorado (unpublished data, Earth Science Laboratory, University of Utah Research Institute).

Geology: Geothermal conditions in Colorado thermal areas vary from a simple stratigraphic section in the Canon City embayment west of Pueblo to the highly complex structure and tectonics of the Curry and Rico areas. Coe (1975) discussed features of a region favorable for commercial geothermal resources and points out that the San Luis and upper Arkansas Valleys (northern Rio Grande rift and peripheral areas in south-central and southwest Colorado) have these features in varying combinations: 1) young volcanic activity, 2) normal faulting, rifting, and extension, 3) thermal springs and wells, and 4) high heat flow above the surface and high thermal gradients above sea level. Butler (1974) analyzes available heat flow, geology, and seismicity data and suggests that the western slope of the Rocky Mountains and the San Luis and upper Arkansas Valleys are optimum for geothermal systems.

Potential uses: In summarizing some potential uses of geothermal resources in Colorado, Coe (1978) lists: power generation (over 200°C); space and water heating and cooling; refrigeration; business processing; feedlot and pen warming; crop drying; agricultural produce processing; manufacturing plywood, veneer, particle board, paper, pulp, and wood-chemicals; milk pasteurization and chilling; mushroom growing; freeze drying; sodium chloride production; natron; and dewatering processing and wood drying. Coe (1978) also shows that in western Colorado 16,000 homes, plus commercial, industrial, and public buildings, could be supplied with space heating and hot water.

Direct thermal use: Coe (1978) points out that Colorado's thermal resources are predominantly low- and intermediate-temperature, and the greatest exploitation probably will be for direct use, mainly space and water heating. Her study shows that in western Colorado, where the main energy demand is for heating residential and commercial buildings, 17 communities are located in thermal resource areas and 23 communities are within 10 miles of them. Exploitation of geothermal energy for space and water heating could help alleviate negative impact of mineral and other energy development at Craig, Poncha, and localities in Routt and Gunnison Counties. Nearby thermal resources can be used for space heat and hot water in tourist-oriented communities such as Steamboat Springs, Glenwood Springs, Pangua Springs, Ouray, and Durango. Extensive use of thermal systems for processing agricultural products appears most likely in the San Luis Valley.

Power generation: Large energy companies have acquired geothermal leases on over 116,000 acres of Federal and State lands, and additional private lands, in Colorado: Mount Princeton, Poncha, and Cripple Hot Springs are currently being evaluated for commercial power generation, and resources appear to be adequate in magnitude and temperature (over 200°C). The Valley View-Hotwater Hot Springs area of northern San Luis Valley has attracted considerable exploration.

Low-Temperature Geothermal Waters
 Area of significant lateral extent favorable for discovery and development of local sources of low-temperature (<90°C) water. Areas are defined on the basis of thermal springs, wells, and geologic settings generally favorable for recovery of thermal water. Existing knowledge does not in general permit the inference that thermal water may be found everywhere within the depicted areas, nor do the boundaries represent certain knowledge of the areal extent of the geothermal systems. Areas are modified from those defined by E.A. Sarnel, Durango and Rico, 1967; and General L.A. Dorrance, 1967. U.S. Geological Survey Circular 790.

Thermal Springs and Wells
 Thermal springs
 Surface temperature >50°C
 Surface temperature >90°C
 Thermal wells
 Surface temperature <50°C
 Surface temperature >50°C
 Temperature: ° Celsius
 Flow: liters/minute
 Total dissolved solids: mg/liter

Known Geothermal Resource Area (GCRAs)
 Designated by the U.S. Department of the Interior. Name in red lettering.
 U.S. Department of Energy Reservation
 Indian Reservation
 Military Reservation
 National Forest, National Grassland
 National Park, National Monument
 National Wilderness Area, National Wildlife Refuge, or State Park
 Private land and area within National Reservations

METRIC CONVERSION FACTORS
 1 liter = 34.6 gallons
 1 meter = 3.28 feet
 1 milligram/liter = 1 part per million
 *Celsius = 5/9 (Fahrenheit - 32)
 *Fahrenheit = 9/5 (Celsius) + 32
