Geothermal Resources of Alaska

1983

Bill Sheffield, Governor
Esther Wunnicke, Commissioner, Department of Natural Resources
Ross G. Schafl, State Geologist, Division of Geological and Geophysical Surveys

Geothermal data compiled and interpreted by the

DIVISION OF GEOLOGICAL AND GEOPHYSICAL SURVEYS
ALASKA DEPARTMENT OF NATURAL RESOURCES

Map produced by the
National Geophysical Data Center
National Oceanic and Atmospheric Administration
for the
Geothermal and Hydropower Technologies Division
United States Department of Energy

Geothermal data compiled and interpreted by Roman J. Motyka, Mary A. Moorman, and Shirley A. Liss of the Alaska Division of Geological and Geophysical Surveys, Fairbanks, Alaska, and by Donald L. Turner, Robert B. Forbes, Mary Albanese, Joyce Macbeth, Andrew B. Lockhart and Stanley M. Seed of the Geophysical Institute, University of Alaska, Fairbanks, Alaska. John W. Reeder of the Alaska Division of Geological and Geophysical Surveys, Eagle River, Alaska, also supplied information. Earlier compilations of the State's geothermal resources by Tom P. Miller of the U.S. Geological Survey (ref. 8) and by Donald R. Mackie of the Alaska Division of Energy and Power Development (ref. 6) provided starting points for this compilation. Heat flow data were provided by the U.S. Geological Survey (ref. 5).

Map available at any of the four ADGCS information offices: Alaska National Bank of the North Building, Geist Road and University Avenue, Fairbanks; 3601 C Street (10th Floor), Anchorage; 230 South Franklin Street (4th Floor), Juneau; and the State Office Building, Ketchikan.

Mail orders should be addressed to: ADGGS, 794 University Avenue (Basement), Fairbanks, Alaska 99701.

Map produced by Ronald H. Smith, Cooperative Institute for Research in Environmental Sciences (CIRES), University of Colorado/NOAA, and Joy Saelman, NGDC/NOAA, Boulder, Colorado, in cooperation with the Earth Science Laboratory/ University of Utah Research Institute, Salt Lake City, Utah.

Digital thermal well and spring data available from GEOTHERM Project, U.S. Geological Survey, 345 Middlefield Road, M584, Menlo Park, California 94025.

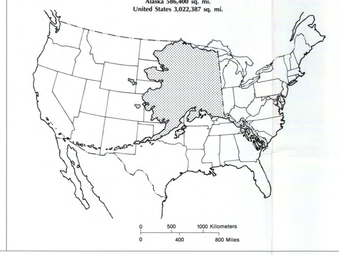
United States 3,022,387 sq. mi.



Introduction

Between 1979 and 1982 the Alaska Division of Geological and Geophysical Surveys (ADGGS) and the Geophysical Institute, University of Alaska, undertook an assessment of the State's geothermal resources under a program jointly sponsored by the U.S. Department of Energy and the State of Alaska. During this period reconnaissance investigations of over 100 thermal spring sites and fumarole fields located in Alaska were conducted by ADGGS. This work included reconnaissance of site geology and hydrology, investigation of thermal spring and fumarole characteristics including temperatures and flow rates, and geochemical sampling of thermal fluids. This map is based largely on information gathered from these reconnaissance studies plus additional information obtained from more detailed studies recently conducted at several of the more promising geothermal areas. Additional background material was provided by previous investigations and compilations of the state's geothermal resources (ref. 6, 8, 20, and 22).

Only a few geothermal areas in Alaska have thus far received any detailed investigation. Areas selected for reconnaissance studies, most of the state's geothermal resources remain virtually unexplored. There is also a lack of public awareness, however, that geothermal resources can play a significant role in meeting the State's energy needs, particularly in rural areas. The primary purpose of this map, therefore, is to aid potential users in developing geothermal resources in a manner beneficial for Alaska.

Data Base

The minimum surface temperature for wells and springs shown on the map is 15°C. The table of thermal springs, wells, and fumaroles has been divided according to four different geographical areas: Alaska Peninsula and Aleutian Islands; SC, south-central Alaska; NC, north-central Alaska; and SE, southeast Alaska. Most of the data on wells, springs, and fumaroles were obtained from recent ADGGS investigations. Some additional data were obtained from published and unpublished works by the U.S. Geological Survey. Both ADGGS and USGS sources are cited in the reference list. Very little geothermal data are available for Alaska; the data that appear on the map were provided by the U.S. Geological Survey (ref. 5).

In the accompanying table of wells and springs, the temperatures reported are the most recent available. Temperatures given for dissolved solids data can vary with time; consequently they should be regarded as approximate. Flow rates are even more variable. Commonly, springs do not flow from a single orifice but from a group of orifices. In these cases, the temperature reported is the highest of the group; the flow rate reported is for the group as a whole. In cases where a group of wells was drilled in a very small area, they are represented by only one symbol on the map, and the temperature reported is the highest for the group. The depth reported is that of the deepest of the group.

Geothermometry

At many sites where data from drilling are not available, subsurface temperatures have been calculated using chemical geothermometers, which are based on temperature sensitive chemical reactions in hydrothermal fluids. These reactions may control either the absolute amount of an element (e.g., silica), relative concentrations of elements (e.g., cations), or fractionation of isotopes. By comparing the results of reactions under known conditions with results of analyses of hydrothermal fluids, an estimated reservoir temperature can be calculated. The estimated temperatures derived from geothermometry calculations may represent actual subsurface temperatures if several assumptions about the nature of an individual hydrothermal system are satisfied.

Resources and Uses

White and Williams (ref. 27) classified geothermal systems according to estimated subsurface water temperatures: those systems having subsurface water temperatures greater than 150°C are classified as high-temperature systems; those with temperatures between 90° and 150°C as moderate-temperature systems, and systems with subsurface water temperatures of less than 90°C are classified as low-temperature systems. Subsurface geothermal reservoirs having water temperatures greater than 150°C are most attractive for generation of electricity, while resources with temperatures less than 150°C are usually restricted to direct-heat applications. In the past much of the industrial interest in geothermal energy in the United States has focused on electrical generation. Although the generation of electricity is a potentially important use of geothermal energy in Alaska, a much greater and more widespread potential use is for direct-heat applications. Such applications include space heating, greenhouses, agricultural operations, aquaculture, and many industrial processes that require heat or cooling. Most of Alaska's geothermal resources are located in remote areas and have thus far seen little or no development. A number of thermal spring sites have a history of recreational use, while in a few cases thermal spring waters have been used to heat dwellings and greenhouses (e.g., Manley, Chena, Circle, Bell Island, Pilgrim, Melozi, and Goddard).

The most promising regions in Alaska for finding and developing high-temperature geothermal resources are regions of Quaternary volcanic activity. These regions include the Aleutian arc, which extends over 2,400 km from Mt. Spurr on the east to Buldir Island on the west; the western Wrangell Mountains of south-central Alaska, which consist of several massive Tertiary-Quaternary volcanic centers; the Edgecumbe volcanic field north of Sitka in southeast Alaska; and the Quaternary volcanic fields on the Seward Peninsula. Akutan Island, northern Unalaska Island, and northeastern Atka Island in the Aleutian Islands are particularly promising for the development and use of high-temperature geothermal resources. All three sites have identified, high-temperature hydrothermal systems located near existing population centers that have well-protected, deep-water harbors. Exploratory drilling for geothermal energy sufficient for generation of electricity is currently underway at the Makushin geothermal area on Unalaska Island. The two sites closest to the Alaska mainland metropolitan area that may potentially have high-temperature geothermal resources are Mt. Spurr and the Copper River basin, west of the Wrangell volcanoes.

Geothermal resources elsewhere in the state appear to be mainly of the moderate- to low-temperature type. A belt of thermal springs extends across north-central Alaska. Most of these springs appear to originate as meteoric waters that circulate and are heated along deep fractures that have developed on the margins of Cretaceous and Tertiary granitic plutons. Thermal spring systems in southeast Alaska appear to have a similar origin. Many of these moderate- to low-temperature sites in Alaska are potentially useful for direct-heat applications. Plans for such applications are under consideration for Pilgrim Springs, Manley, Circle, Chena, Goddard, Tenakee, and Bell Island.

Availability of Additional Data

Detailed chemical data for most thermal springs, wells, and fumaroles shown on this map and further information on Alaska's geothermal resources can be obtained by contacting GEO-THERMAL PROGRAM, Alaska Division of Geological and Geophysical Surveys, 794 University Ave. (Basement), Fairbanks, Alaska 99701. Information on drilling requirements and leasing in geothermal areas may be obtained from the Alaska Division of Minerals and Energy Management, 555 Cordova St., Pouch 5-007, Olympic Building, Anchorage, Alaska 99510.

There are several thermal spring sites and fumarole fields that are known to exist but have not yet been visited by ADGGS because of their remote location, their occurrence in a federally designated wilderness area, or because of lack of time. In particular, geothermal resource sites west of Adak Island have not yet been explored by ADGGS. Much of Alaska remains in a wilderness state and it is probable that additional thermal spring sites exist but have not been discovered or reported. Persons who can provide additional information on thermal springs, wells, and fumaroles in Alaska are encouraged to contact the Alaska Division of Geological and Geophysical Surveys so that our geothermal files can be updated.

Land Status

With 375.3 million acres of land, Alaska is about one-fifth the size of the conterminous United States. Ownership of Alaska's lands

Thermal Springs and Wells

Thermal springs
- Surface temperature unknown
- Surface temperature 50°C or lower
- Surface temperature higher than 50°C

Thermal wells
- Surface temperature 50°C or lower
- Surface temperature higher than 50°C

Heat Flow

50-75 ▲ Geothermal gradient test hole (range of heat flow values in milliwatts/meter² shown for individual wells)

(See Lachenbruch, and Moses, 1979 (ref. 5))

Thermal Waters

Light gray. Region of Alaska favorable for the discovery at shallow depth (less than 1000m) of thermal water of sufficient temperature for direct-heat applications. It is probable that only small areas of this region are truly underlain by such thermal water; the region represents that part of the state that deserves exploration for thermal areas. The region is defined on the basis of various geothermal and tectonic phenomena such as locations of thermal wells and springs, above-normal heat flow, youthful volcanism, mineralization, and seismicity.

Tectonics and Volcanism

- Faults, dotted where concealed or inferred
- Quaternary or Quaternary-Tertiary volcanic rocks
- Volcanic vent

(See Beikman, 1980 (ref. 1))

Base Map Explanation

- Known Geothermal Resources Area (KGRA) as designated by the U.S. Department of Interior. Name in red lettering.
- Military reservation
- National forest or state forest
- National park, national monument, national wilderness area, national wildlife refuge, or state park

Private lands may exist within federal boundaries

- State highway
- Other principal road

Metric Conversion Factors

1 liter= .2642 gallon
1 meter= 3.281 feet
1 milligram/ liter= 1 part per million
°Celsius= 5/9 (°Fahrenheit – 32)
°Fahrenheit= 9/5 °Celsius + 32

Notes
- When numbers, spring can present, position a middle location
- Temperature is given for highest spring or spring with highest flow.
- asterisk (*) indicates highest recorded fumarole temperature
- Field measurement
- Computed value
- Reported or estimated
- Dash (-) indicates data unavailable
