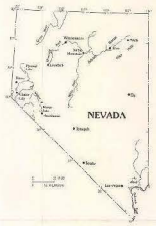

FIGURE 1.—Location of study area

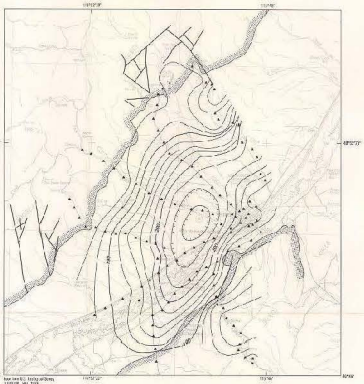

FIGURE 2.—Bouguer gravity values

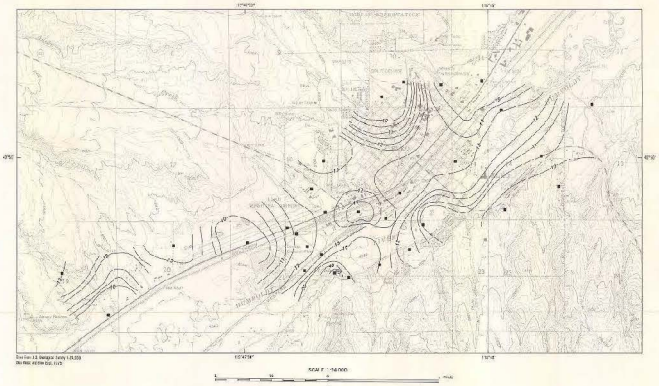

FIGURE 4.—Soil temperature at a depth of 6.6 feet.

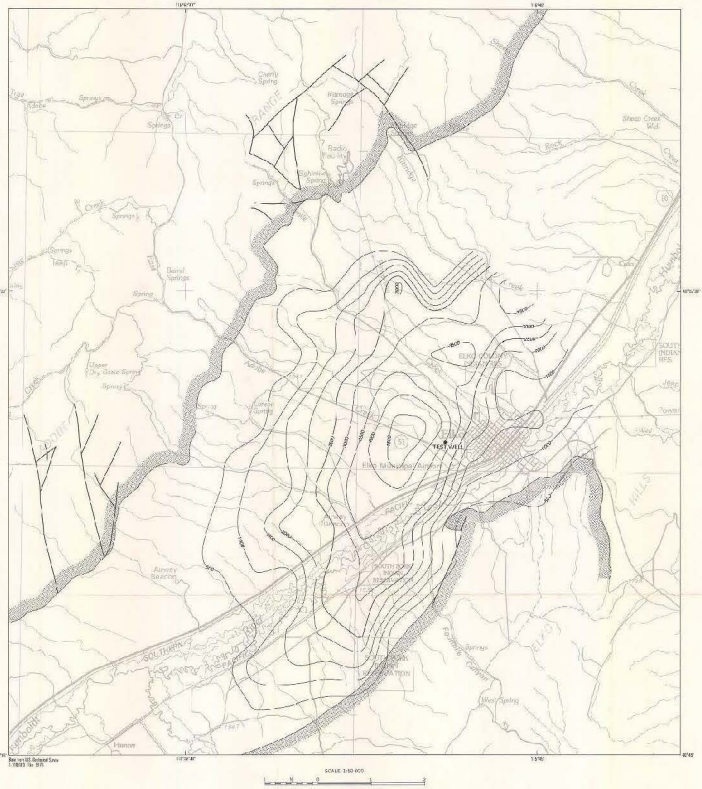

FIGURE 3.—Depth to consolidated rock

EXPLANATION FOR FIGURES 2, 3, AND 4

Consolidated rocks

Valley-fill sedimentary rocks and deposits

Gravity measurement station (figure 2)

Temperature measurement site (figure 4)

—250— Line of equal Bouguer gravity (figure 2). Hachured line indicates enclosed area of relative gravity low. Interval 2 milliGals

—500— Line of equal depth to consolidated rock (figure 3).—Interval 500 feet. Dotted where buried

—70— Line of equal temperature at 6.6-foot depth (figure 4).—Interval 2 degrees Celsius (C) or variable

Fault

CONVERSION FACTORS AND ABBREVIATIONS

"Inch-pound" units of measure used in this report may be converted to International System (metric) units by using the following factors:

Multiply	By	To obtain
Feet (ft)	0.3048	Meters (m)
Miles (mi)	1.609	Kilometers (km)
Square miles (mi²)	2.590	Square kilometers (km²)

For temperature, degrees Celsius (°C) may be converted to degrees Fahrenheit (°F) by using the formula °F = (1.8 °C) + 32.

ABSTRACT

The Elko area, a semi-arid area in Nevada, has a beneficial ranching and mining industry. Elko and its environs are in the valley of the Humboldt River, which is underlain by as much as 4,000 feet of valley-fill sediments. The valley-fill deposits are underlain by consolidated rocks that crop out in the mountains that surround the valley.

The depth to consolidated rock was estimated from gravity measurements. Depths were calculated using a three-dimensional gravity model of consolidated and unconsolidated rocks. Control for the model was provided by data from 11 deep test wells and from 200 gravity measurements. Depths to consolidated rock were calculated at 1,000-foot intervals in a grid that covered the valley and adjacent mountains. The calculated depths to consolidated rock were then contoured to show the configuration of the bedrock surface.

The deepest part of the valley is in the northern part of the area, where the consolidated rock surface is more than 4,000 feet below sea level. The valley is relatively shallow in the southern part of the area, where depths to consolidated rock are generally less than 1,000 feet below sea level.

Soil temperatures were measured at a depth of 6.6 feet (2 meters) at 200 sites in the valley. Temperatures ranged from 8°C to 16°C. Temperatures were generally highest in the central part of the valley and lowest near the mountains. Temperatures were also relatively low in the northern part of the valley, where the depth to consolidated rock is greatest.

INTRODUCTION

The Elko area, approximately 250 miles northeast of Reno, Nevada (figure 1), is a principal mining and ranching center in northeastern Nevada. The area is underlain by as much as 4,000 feet of valley-fill sediments. These sediments are underlain by consolidated rocks that crop out in the mountains that surround the valley. The valley-fill deposits are the principal source of water in the area.

The Elko area is in the valley of the Humboldt River, which flows northeastward across the area. The Humboldt River valley is a structural trough that is bounded on the northwest by the Adobe Range and on the southeast by the Ruby Mountains and the East Humboldt Range. The valley is about 10 miles wide in the Elko area and narrows to the northeast and southwest.

The Elko area is in the Basin and Range physiographic province. The province is characterized by numerous mountain ranges that are separated by broad, alluvium-filled valleys. The mountains generally trend northeastward and rise as much as 5,000 feet above the valley floors
